Addressing Tobacco Use with Improved Utilization of 5As Framework in Primary Care

Binta Bojang

School of Nursing, Eastern Kentucky University

DNP Project

April 17th, 2022

Abstract

Identifying and treating tobacco use disorder through screening and evidence-based intervention is necessary to assist all tobacco users to quit and or to decrease typical tobacco-linked health risks. The findings from the literature review suggested that the implementation of the technology-enhanced 5As model (asking, advising, assessing, assisting and arranging for follow up) approach might serve as a reminder to clinicians to assess tobacco use, and improve patient outcomes in tobacco cessation care. The purpose of this DNP project was to improve the treatment of tobacco use disorder among adults in a primary care. The objective of this project was to develop and implement a tobacco cessation program protocol using the Computer Facilitated 5As (CF5As) model in the clinic within 12 weeks. The Readiness for Implementing Change (ORIC) tool was done to assess the organization's readiness for practice change. The Computer Facilitated 5As Model was implemented in primary care clinic after staff education and monitored for 12 weeks. The findings revealed that implementing the Computer Facilitated 5As model increased asking, advising, assessing, assisting, and arranging for follow-up by clinicians to achieve tobacco cessation treatment among adults.

Addressing Tobacco Use with Improved Utilization of 5As Framework in Primary Care

Tobacco use-related illnesses are one of the leading causes of morbidity and mortality in the United States. There is an increasing need to develop sustainable interventions that can reduce tobacco use and sustain the number of people who have quit (Centers for Disease Control and Prevention [CDC], 2019). This objective is particularly important because smoking and smokeless tobacco users are at risk for cancer, cardiovascular diseases, strokes, chronic obstructive pulmonary diseases (COPD), lung failures, and many other comorbidities and negative sequelae (CDC, 2019). The purpose of this DNP project was to improve clinician screening and treatment of tobacco use disorder through improved utilization of the 5As (Ask, Advise, Assess, Assist, Arrange) Framework in a primary care clinic.

Background and Significance

Incidence

Tobacco use remains one of the leading preventable causes of death globally. According to the World Health Organization (WHO) (2020), greater 8 million people die yearly due to tobacco use related illnesses. Furthermore, deaths continue to rise and may hit over 8 million by 2030 (WHO, 2020). Both smoke and smokeless tobacco cause significant health consequences including deadly cancers (WHO, 2020). Tobacco use and addiction remain the leading factor in disease burden, affecting approximately 15.3% for men and 12.7% for women (Mediratta & Poullis, 2016).

Nationally, tobacco use-related diseases are among the leading causes of morbidity and mortality in the United States. According to the CDC, approximately 14% of all United States adults use tobacco products which are well-known implications for chronic illnesses. Yearly deaths of up to 7 million people from smoking-related diseases, especially cancer, cause an

overload on medical facilities and result from failed early medical intervention programs. The mortalities threaten the economy's sustainability and strain the medical financing of our nation. Tobacco-related illness in the United States costs more than \$300 billion a year (CDC, 2019). An estimated 1,600 people try their first smoke every day, with most progressing into habitual smokers and eventually leading to addiction (CDC, 2019).

Locally, about 13.9% of adults in Maryland smoke tobacco products and 4.9% of adults use smokeless tobacco. Tobacco related healthcare treatment cost the State of Maryland \$2.71 billion per year. The state experiences about 7,500 tobacco related death each year (Maryland Department of Health, 2018).

Screening

Health care providers can have a vital role in decreasing tobacco use. For example, face-to-face visits with clinicians can facilitate a seven percent tobacco cessation rate within a year without a tobacco cessation intervention (Mediratta & Poullis, 2016). Research has shown health care practices that provide cessation interventions and close monitoring show an even more significant increase, about 18% to 23% in quit rates among their patients (Mediratta & Poullis, 2016). It is recommended that at every clinical encounter, providers screen all adult patients for tobacco consumption and dependence, and provide evidence-based treatments for those who use tobacco products (Clinical Practice Guideline Treating Tobacco Use and Dependence (Fiore, et al., 2008)

Most smokers are frequent users of healthcare services, and their contact with the health system can facilitate a road to complete abstinence (CDC, 2019). The primary care clinic encounter particularly can provide a unique opportunity to screen, identify and engage smokers, initiate cessation treatments, and provide appropriate follow-up and support.

Treatment Approach

The United States Prevention Services Task Force (USPSTF) encourages a counseling framework that is well-known as the 5As Framework. These steps involve Asking every patient about tobacco consumption, Advising patients to quit, Assessing motivation to quit, Assist with interventions, and help Arrange for follow-up and support (Fiore, et al., 2008). This Grade A recommendation is founded on high certainty that the net benefit is significant. The approach includes implementation of a tobacco user detection system, promotion of provider intervention through resources, education and feedback, identifying and propositioning staff members to provide the treatment, and assessing staff performance in the delivery of treatment (Fiore, et al., 2008). There are well-accepted and evidence-based tobacco cessation tools in the literature that have proven to be effective in the clinical settings. Unfortunately, data suggest that consistent cessation treatments are not being provided. Additionally, those who quit without assistance are more likely to slide back into tobacco use than those assisted by clinicians (Park et al., 2015).

Many studies and literature reviews that have shown brief interventions by clinicians should cover the 5As of tobacco cessation treatment. Park et al. (2015) did a matched case-control study on 3336 National Lung Screening Trial (NLST) participants. The primary purpose of the study is to determine the relationship between the reported clinician-delivered 5As model (ask, advise, assess, assist and arrange) after lung screening and smoking patterns. The study revealed that ask, advise, and assess have not been significantly associated with tobacco abstinence. The researchers reported increased quit rates among participants who received multisession and more intensive visits that included providing assistance and arranging follow-up (Park et al., 2015). The providers fall short in the last 2 steps, creating an opportunity to improve.

Proposed Evidence-Based Interventions

As mentioned above, tobacco use remains one of the major contributors to chronic diseases, unfortunate deaths, and financial burden at both the state and national level. It is generally accepted that most tobacco users make several quit attempts before they are successful, yet only a small percentage of those who attempt to quit without any cessation assistance succeed (Moody-Thomas et al., 2015; Satterfield et al., 2018). In this regard, healthcare providers have a pivotal role in reducing tobacco use by implementing various evidence-based interventions. The 5As model for tobacco cessation was issued by World Health Organization in 2014 to help clinicians effectively improve their knowledge and skills of treating tobacco dependence (WHO, 2014). The model has shown to be a cost-effective, efficacious, evidenced-based process for health care provider provision of tobacco cessation support. Most healthcare providers across the country have adopted the 5As in trying to assist tobacco users (WHO, 2014).

Effective interventions are available to support all tobacco users who want to quit; however, their delivery in the primary care setting is ad hoc and inconsistent without proper clinical protocol (Mediratta & Poullis, 2016). The increased associated risk of morbidity and mortality for tobacco users may decrease through dependable delivery of the 5As tobacco cessation program in a primary care setting. Therefore, the implementation of tobacco cessation in the primary care setting is highly needed to improve tobacco screening and tobacco cessation interventions.

Literature Review

A formal review of the literature was conducted to answer the question, "Will reminding clinical staff about 5 A's strategy via the EMR (I) improve screening (O) and treatment (O) of

tobacco dependence among adult patients (P) in the primary care setting within 12 weeks (T)?” The database search was conducted using Cochrane Library, MEDLINE, Nursing & Allied Health Database, and PubMed. The keywords used were *tobacco cessation, tobacco use treatment, tobacco screening, and 5 A’s strategy reminders*. The article search was narrowed to English-only free full text, and adults aged 18 to 65 years published from 2015 to 2020. A total of 36 articles was found and further narrowed to 6 articles by a hand search of abstract. All evidence was critically appraised using the Melnyk-Fineout Overholt Rapid Critical Appraisal Forms (Appendix A, B, C).

Guidelines and Use in Practice

The Clinical Practice Guideline for Treating Tobacco Use and Dependence recommended the use of brief interventions like the 5As because they are more effective, especially when faced with constraints to time and resources (Fiore, et al., 2008). The 2008 update to this guideline particularly summarizes recommendations from an independent panel of 24 scientists and clinicians on the topic of tobacco cessation. This guideline analyzed more than 8700 peer-reviewed journals between the years 1975 and 2007, aiming to understand how tobacco dependence has been addressed over time. After thorough panel meetings and conference calls, the guideline synthesized the results and developed recommendations which were then reviewed by more than 90 experts. The guideline concluded by recommending brief tobacco cessation interventions and system-level changes that would help in screening and treatment. The extensive review of screening and treatment interventions over time as outlined in this guideline will help in contextualizing the expected outcomes for this DNP project and its future application as evidence-based practice.

Importance of Electronic Medical Record

The employment of a custom-made Electronic Medical Record (EMR) reminder approach can help with a smoking cessation program. EMR can be helpful to timely prompt clinicians to assess for and document tobacco use. It can also help to prompt clinicians to treat accordingly. Bar-Zeev et al. (2019) conducted a meta-analysis and systematic review to improve smoking cessation by health providers among pregnancy women in a primary care setting. The researchers collected data from five databases and included all the components of the 5A intervention model. They also used the Effective Practice of Care taxonomy to characterize the interventions. The included studies were assessed using the Cochrane Collaboration for assessing risk bias, and the Hawker Quality assessment tool. The analysis revealed that interventions for smoking cessation at any preventative care settings have significant effect on tobacco cessation.

Delivery in Primary Care

Moreover, many studies have proven that tobacco cessation treatments can be effectively delivered in a primary care setting. Wray et al. (2018) did a meta-analysis to examine tobacco cessation programs' efficacy in different integrated primary care clinics. In this review, 36 studies were included and up to 12,975 patients. Over 58% of the studies implemented interventions such as cognitive behavioral therapy, the 5As model with straightforward advice, motivational interviews, and health education. Forty-two percent of the studies utilized both the interventions mentioned above and pharmacological treatment (Bupropion SR, Nicotine products, and Varenicline). Eighty-three percent of all studies lasted over six months with at least 3 follow up appointments. The meta-analysis revealed that those who received multiple interventions (non-pharmacological and pharmacological) have a higher chance of tobacco abstinence (1.78 Odds Ratio (OR), confidence interval (CI) 95%) compared to those who receive just received non-pharmacological.

Despite concluding that brief interventions were effective, this review was constrained by limitations of publication bias and sample heterogeneity, both of which factors compromised statistical interpretation. Notwithstanding, Wray et al. (2017) recommended that future research evaluate ways of improving the dissemination of brief interventions in such integrated primary care settings. Considering this recommendation, for effective application in evidence-based practice, the current DNP project seeks to suggest ways of fully utilizing the 5As framework in primary care.

5As Embedded in EMR

Likewise, embedding the 5As tobacco treatment model in the EMR could improve the use of clinical practice guidelines to help increase tobacco abstinence among users. The randomized controlled trial (RCT) by Satterfield et al. (2018) assessed both the efficacy of computer-facilitated 5As for smoking cessation treatment and the adherence by primary care providers. Satterfield et al. (2018) used a cluster RCT design on primary care providers in three urban adult primary care clinics. Study participants were characterized by the criteria of having smoked more than 100 lifetime cigarettes and had at least a cigarette the past week. The patients were assessed and randomly assigned to Computer-Facilitated 5As (CF5As) or usual care based on providers' assignments. The study randomized providers (n=221) who provided care to patients in the intervention group (n=412) and in the control group (n=549). The study revealed the intervention group providers had significantly higher odds of completing all 5A's (2.04 Adjusted Odds Ratio (AOR), CI 95%) compared to the usual care group, suggesting that EMR will increase screening and treatment (Satterfield et al., 2018).

The authors concluded that 5As were a low-cost, time-saving intervention effective at improving smoking cessation care and addiction. As such, this study can help the current DNP

project demonstrate the efficacy of 5As in the primary care environment. One limitation was the study relied on patient self-reporting that could distort actual results. To avoid the bias that this issue creates, the focus will remain on primary care providers' perspectives and various follow-up mechanisms to better assess intervention efficacy.

Implementing the 5As

Next, a study done by Moody-Thomas et al. (2015) demonstrated effective implementation of the 5As treatment model can improve tobacco use quit rate. In this study, the researchers sought to determine the effects of changes in the system and electronic medical records in assisting tobacco smokers in quitting. The data was collected from 79,777 patients who had visited primary care providers for tobacco cessation between January 1, 2009, and January 31, 2012. With the use of the EMR system prompts, the healthcare providers screened and advised 95.8% of their patients to quit tobacco use. The researchers concluded that electronic health records could be a useful clinical intervention leading to reductions in tobacco use and sustained quits. The study's strength was using large sample size and a high confidence level of 95%. The study revealed 9.5 % relative reduction among tobacco users after the 3-year study period.

This study has the potential to support the current DNP project because the research emphasizes the utility of existing technological resources to improve the effectiveness of smoking cessation treatment in primary care settings. However, the study was compromised by two factors: the difficulty to determine the quality of EMR data and patients' tendency to self-report more positive assessments of their tobacco use. To avoid these challenges, this DNP project will examine the personal, environmental, and cognitive factors related to tobacco use in

the primary care environment before testing the effectiveness of the technology facilitated 5As model in a primary care clinic.

EMR can also be advantageous to provide a view on tobacco screening and treatment performance. Another study by Napoles et al. (2016) assessed the perceptions of clinicians and staff about the use of digital technology in primary care. This qualitative study, used a computer-facilitated 5As model to identify conditions, based on the perspectives of primary care providers and clinical staff, would be necessary to facilitate the introduction of digital technology to smoking cessation care. This study was based on the semi-structured interviews of 10 clinical, 12 administrative staff, and 13 primary care providers from three primary care clinics. The interview questions focused on the following items: potential gains in counseling efficiency, relevance for various health behavior counseling programs, confidentiality of data collection from patients, occupying patients while waiting, and serving as a cue to action. The results of this study showed the perceived ease of digital technology use was viewed as dependent on patient characteristics, clinic workflow, and patient volumes.

Synthesis of Literature

Technological tools and resources have the potential to offer efficient alternatives to conventional behavioral counseling mechanisms, primarily by addressing specific challenges of knowledge, resources, communication, and time (Napoles et al., 2016). While brief clinical interventions like those supported by the 5As framework can be implemented to reduce tobacco-related chronic diseases and deaths, current literature indicates a need for systemic change in health organizations to support delivery of these evidence-based tobacco dependence therapies (Satterfield et al., 2018; Wray et al., 2018).

Considering the above synthesis, more comprehensive knowledge is required by healthcare professionals to effectively implement and avail of the 5As strategy to screen for and prevent tobacco dependence. Four of the studies discussed computer-facilitated 5As service delivery models currently used in primary care clinics; one study mentioned the combination of the 5As model with motivational interviews, health education, cognitive behavioral therapy, and pharmacological therapy; another study mentioned a computer-mediated 5As service delivery model in inpatient and outpatient primary care settings. The Clinical Practice Guideline Treating Tobacco Use and Dependence recommended the use of a brief interventions model during patient encounters.

Ultimately, and for application of the current DNP project in evidence-based practice, synthesis of these findings suggests that the implementation of brief interventions, like that supported by the 5As model, and the integration of technology-enhanced behavioral counseling interventions, will significantly serve as reminders, and improve patient outcomes in smoking cessation care.

Guiding Theory

Pender's Health Promotion Model, developed by Dr. Nola Pender in 1982, is an effective theoretical framework that healthcare professionals can use to help patients attain improved health status (Pender & Pender, 1996). The theory contains various concepts and components whose understanding helps in equipping clinicians with the necessary knowledge, skills, and experience needed in addressing patients' needs. The model can be used in diagnosing, treating, and managing a wide range of health conditions, including tobacco use disorder (Pender & Pender, 1996). This model's utilization within this DNP project will help the clinic staff

understand the leading determinants of health behaviors as the basis for behavioral counseling and promoting well-being (Pender & Pender, 1996).

The theoretical model works on four beliefs that play a vital role in informing its philosophical foundation. First, Pender's Health Promotion Model assumes that all people strive to control their health behaviors (Pender & Pender, 1996). Secondly, the model hypothesizes that people in their different bio-psychosocial complexity tend to interact with their environment in a progressive way that, in turn, helps to transform themselves and their surroundings. Thirdly, health professionals, including nurses, form a vital part of the interpersonal environment, affecting people's behaviors throughout their lifespan (Pender & Pender, 1996). Lastly, the self-initiated transformation and unique environment interactive patterns are critical to changing people's actions.

Additionally, Pender's Health Promotion Model has three major concepts (Pender & Pender, 1996). Individual characteristics and experiences refer to the unique personal features that affect the actions taken by people. Such attributes include prior related behaviors and their associated personal factors (Pender & Pender, 1996). Health Cognitions, on the other hand, are the variables that are specific to certain behaviors. The behavior-specific cognitions and affect comprise of the perceived benefits that a person has towards a particular action, its associated barriers, self-efficacy, situational and interpersonal influences, and affect resulting from various activities. Therefore, people can change such factors by using appropriate nursing actions to attain better health status (Pender & Pender, 1996). Lastly, behavioral outcomes are the acceptable and anticipated actions that people changing their risky practices must depict.

It is essential to have a comprehensive strategy and action plan when using this model to improve the screening of tobacco use and cessation treatment among adult patients in primary

care clinics. This identification should involve selecting patients on personal factors, including biological, psychological, and socio-cultural factors. The staff used this model as a guide to assess readiness to quit, preferences on the types of intervention, and the barriers that could hinder patient from utilizing the available screening services.

Organization Description

Setting and Mission

This DNP project was implemented in a primary care clinic in Baltimore, Maryland. The clinic is part of a small community hospital utilized mainly for primary care services. The organization's mission is to improve the health of those they serve at the individual and community level with compassion and quality of care.

Patient Population Served

The practice provides internal medicine services to adult patients aged 18 and above. A significant population of the clinic is the underserved minority population. Most of patients have Medicare and Medicaid insurance. Few uninsured patients are seen without charges for post-hospital discharge follow-ups. Patients were mostly seen on an appointment basis with few walk-ins for minor urgent care needs.

Stakeholders

The inclusive stakeholders were the clinic staff, technology department, billing department, patients and their family members, and the organization leaders. These stakeholders helped facilitate the development and implementation of the program and ascertained it through to the completion stages. The medical practitioners, medical assistants, nurses, and case managers collaborated amongst themselves to facilitate the critical program needs. The Principal Investigator (PI) was available on site and or by email or phone for support.

Target and Impact Population

This quality improvement project's target population was the clinic medical providers, nursing staff, medical assistants, front desk staff, case manager, and leadership. The impact population was active tobacco user patients.

Organizational Assessment

The organization uses an EMR system that helped to prompt staff to assess and treat tobacco use disorder. The clinic has about 800 active patients, and 11 medical providers perform about 70 to 85 face-to-face encounters a day except on Saturdays. The SWOT Analysis (Appendix D) illustrates the strengths, weaknesses, opportunities, and threats of this DNP project within this organization. Notably, the clinic has strong leadership with excellent interpersonal skills that helped influence staff compliance. The implementation of this DNP project has faced internal threats such as current staff use of tobacco products and staff's personal bias about tobacco cessation.

Additionally, according to the Clinical Practice Guideline Treating Tobacco Use and Dependence Update Panel by Fiore et al. (2008), tobacco counseling and or discussion of treatment requires more time than a regular patient visit. The clinic must increase encounter time and frequency for tobacco users, which may lead to fewer patients seen in a day and, in turn, might decrease revenue for the clinic. Also, some patients have high deductible and co-pay, and might not afford more frequent visits for continuous monitoring and evaluations. Nonetheless, external pressure to prioritize preventative care, including tobacco screening and treatment by the department of health in Maryland, was a favorable factor for this DNP project. The project's external threats included peers or family members of a patient who use tobacco products, social determinants of health, and myths associated with tobacco cessation.

Congruence of Project to the Organization

One of the clinic's objectives was to increase tobacco screening and treatment by the clinician to improve health outcomes and maintain certification for the Maryland Primary Care Program (MDPCP). The MDPCP is a voluntary program for interested organizations that aim to provide a higher standard of preventative care and lowering the cost of healthcare. The program encourages an extensive preventative care model and chronic care services to reduce hospitalization and increase health outcomes. It provides funding and support for all certified primary care centers within Maryland (Maryland Department of Health, 2020). In collaboration with both the State's Medicare and Medicaid regulation for MDPCP, the organization desires to help prevent disease and reduce cost, which is inclusive of tobacco use disorder.

Methodology

Aims and Objectives

This DNP project aimed to increase the utilization of 5As five-step tobacco cessation screening by incorporating the elements into a computer-based template.

Objective One

The first objective was to develop and train the staff on tobacco cessation program protocol using the Computer Facilitated 5As model in a primary care clinic within 12 weeks. As a component of this training, the Organizational Readiness for Implementing Change (ORIC) questionnaire was administered to assess readiness for the practice change. Findings from the survey was taken into consideration to promote the success of the practice change implementation.

Outcome: Seventy percent of staff will feel confident by indicating “somewhat agree” or “agree” and commit to the implementation of the tobacco cessation program within the clinic to improve patient care.

Objective Two

The Computer Facilitated 5As Model was implemented in the targeted primary care clinic. The outcome measurements of this objective were documented in the electronic chart as follows over a period of 12 weeks:

1. Triage nurses will **Ask** all adults about tobacco use status 75% of the time and document patient response.
2. Triage nurses will **Advise** and **Assess** for willingness to quit for all active adult tobacco user patients 75% of the time and document the patient response.
3. Health care providers will **Assist** all active tobacco users who express willingness to quit with counseling and or prescribing the FDA approved medication (Appendix E) treatment 75% of the time and document their treatment plan.
4. Health care providers will **Arrange** at least one follow-up for those patients who express willingness to quit 75% of the time and document their treatment plan.
5. Health care providers will select appropriate diagnostic, procedure, and billing codes (Appendix F, G) based upon the documentation as related to findings and care provided 100% of the time.
6. Data collected from the pre, and post 5As utilization questionnaire (Appendix H) will increase by 50% over baseline.

Design and Implementation Framework

The design of this DNP Project was a quality improvement initiative focused on implementation of evidence-based project. The IOWA Model Framework guided the implementation of this DNP project (Appendix I). The IOWA Model is an evidence-based framework designed to guide clinicians in implementing an evidence-based project (Iowa Model Collaborative, 2017). This model emphasizes the significance of considering the entire organization, including the patients and the infrastructure and using research to channel practice decisions. The IOWA model has identified seven significant steps to facilitate engagement in problem identification and solution development related to integrating evidence findings into practice (Iowa Model Collaborative, 2017).

The first step in the Iowa Model is identifying a problem or a trigger that calls for a change in practice or process improvement. Secondly, the model stress that it is crucial to assess the priority nature of the identified problem to the organization. Once the problem is identified and its level of priority is determined, a team selection and collaboration are executed to establish support for the project. The priority problem identified within this organization inconsistent provider screening and management of tobacco use disorder. Consequently, providers were not documenting treatment and billing of tobacco use disorder leading to poor health come and revenue lost for the organization. The third step is team formation. The team of this evidenced based project was the DNP student (PI), DNP team, clinical and nonclinical staff in the clinic, technology department, and the patients.

The fourth step in the Iowa Model EBP involves literature search and synthesis related to the topic, which has been conducted to determine whether there is sufficient evidence to implement the project. Literature review and synthesis suggests that the implementation of brief interventions, such as the integration CF5As serves as reminders, and improve patient outcomes

in tobacco cessation care. The last two steps involve implementing the project and monitoring the outcome (Iowa Model Collaborative, 2017). The project was implemented and successfully monitored and evaluated using the Iowa Model.

Setting

This project took place at outpatient primary care clinic in Woodlawn Center, Baltimore, Maryland.

Recruitment

The PI recruited participants through convenience sampling. The PI had a brief staff meeting with the staff on duty during break period and verbally asked for volunteers to participate in the quality improvement project. A flyer with the project detail (Appendix J) and a recruitment script (Appendix K) was given to each potential participant. The flyer was also printed and posted at different locations within the clinic for easier access. The target population was the entire clinic staff (N = 30) in different roles, and the recruitment target was 30 participants. The inclusive criteria were all active staff, including medical doctors, nurse practitioners, physician assistants, nurses, medical assistants, receptionists, radiology technicians, manager, billing staff, active patients 18 years and older, and patients seen within the project's 12 weeks implementation phase. Exclusive criteria were the volunteer staff, employees younger than 18 years, patients younger than 18 years, and non-active patients. A formal informed consent form was given but signature was not required. This DNP project has minimal risk and very minimal ethical issues. Also, it involved practices that were already in place and did not include experimental intervention. Therefore, a Request for Waiver (Appendix L) was submitted to ECU IRB and was approved.

Intervention

The PI provided one-page of detailed education (Appendix M) regarding the treatment of tobacco use disorder with the utilization of the 5As framework at individual staff convenience time and during their break period. The project workflow (Appendix N), and one-page patient education (Appendix O) was placed at each workstation for easier access and referencing. Each participant was given the Background Survey and the baseline 5As Utilization Questionnaire to complete before the educational session. After the detail education, participants were asked to complete the 12 item ORIC tool to assess for their commitment and confident in the project.

During the project implementation, triaging staff asked every adult patient for tobacco use status. These staff further advised active tobacco users on the benefits of quitting tobacco use and assessed their willingness to quit. Providers reviewed and acknowledged in the chart that tobacco use disorder has been assessed. Additionally, the providers assisted all the patients who expressed willingness to quit by providing counselling and or FDA approved nicotine replacement therapy (Appendix E). Furthermore, providers were asked to document individual plan of care, appropriate diagnostic, and procedure codes (Appendix F, G) based upon the documentation related to findings and care provided. At the end of the project, the participants were asked to complete the posttest 5As Utilization Questionnaire to assess project performance.

Ethical Considerations and IRB

The partnering organization designated ECU to be the IRB of record (Appendix P). The PI applied for an expedited Institutional Review Board (IRB) approval at the Eastern Kentucky University IRB before implementation. The IRB approval for the project was received before the implementation. The project involved practices that are already in place and did include experimental intervention. Therefore, there was minimal risk and very minimal ethical issues. No

personal protected information of staff and or patients was collected during the entire pre- and post-intervention data.

Measurement and Tools

Background Survey. The PI collected participants' background information (Appendix Q) which included age, level of education, role, level of experience, length of employment and employment status. The Background Survey information allowed the PI to better understand background characteristics of the participants which was analyzed using measures of central tendency.

Organizational Readiness for Implement Change. The PI utilized Organizational Readiness for Implementing Change (ORIC) tool to assess the organization's readiness for the DNP project. The ORIC tool (Appendix R) is a multi-faceted and multilevel strategy that requires members to determine with the system to implement a change to prevent project failure (Shea et al., 2014). According to Weiner (2009), the effectiveness of a project depends on team readiness which means the team is agreeing to the project. The degree to which team members perceive a change as essential, needed, and worthy influenced their confidence and commitment (Weiner, 2009).

Shea and colleagues later developed and evaluated the tools to establish their reliability and validity (Shea et al., 2014). The ORIC questionnaire has 12 items that relate to the content of commitment and confidence of the staff. The tool has five items of commitment and seven items of change efficacy assessment. The statements in 1, 3, 5, 7, 8, 10, and 12 assess for confident, and statements in 2, 4, 6, 9, and 11 assess members' commitment. The items are assessed using the 5-point Likert scale from disagreeing to agreeing.

Shea et al. (2014) conducted four studies to evaluate the validity and reliability of the ORIC measurement tool. The researchers evaluated the tool at both individual and organizational levels. In study one, groups were asked to answer each item, and individuals did study 2, 3, and 4 at different locations. The result revealed that reliability for the change commitment and change efficacy scales were more robust at the organizational level ($\alpha = .98$ and $\alpha = .97$, respectively) than at the individual-level ($\alpha = .72$ and $\alpha = .51$, respectively). However, the result provides psychometric evidence supporting the ORIC stool to be helpful at all levels. It also revealed that the items and scales utilize in the ORIC tool can determine the members' readiness and ultimately guide healthcare organizations in implementing a change (Shea et al., 2014). Therefore, the DNP project participants will be asked to complete the ORIC questionnaire after staff education to assess their commitment and motivation for the project.

Since the researchers reported the individual-level assessment variance at 72% and 51% (change commitment and change efficacy), the PI set a goal to obtain at least 70% of staff to feel confident by noting "somewhat agree" or "agree" and commit to the project implementation.

5As Utilization Questionnaire. The PI asked nurses, medical assistants and providers to complete a pretest before the detail educational session to assess their current knowledge and performance of the 5As model. At the end of the DNP project, the staff were asked to complete posttest Utilization Questionnaire to determine their performance. The nurses and medical assistants were asked to complete items A - E, and providers were asked to complete the entire questionnaire, items, A - J. The objective of the detailed education is to enhance the proficiency of the clinic staff in assessing and treating tobacco use disorder. The education was based on the utilization of the 5As within the EMR and the workflow of the project.

Project Evaluation. The data obtained from the background survey and pre-posttest was evaluated using descriptive statistics into recordable observations. This data included the participant's age, level of education, role, and length of employment, employment status, and experience using the 5As approach. Another project data collected and evaluated include the frequency rates of Ask, Advise, Assess, Assist, Arrange, and Current Procedural Terminology (CPT) and Diagnosis Codes. This data was retrieved through hand chart auditing and data download from the EMR.

Audits and Benchmarking. The PI performed a random chart audit of 30 patients on different days before the project go-live to establish baseline performance capturing. Performing the chart audit on different days enabled performance capturing from multiple staff. The PI also performed a random chart audit of 30 patients in weeks 6 and 12 of the project implementation to monitor progress at different intervals. The data collected from the chart audits included the frequency rates of Ask, Advise, Assess, Assist, Arrange, and Current Procedural Terminology (CPT) and diagnosis codes. The data collected was recorded on a spreadsheet (Appendix S).

Data Analysis

Data collected from the Background Survey and the chart audits was entered into an excel spreadsheet (Appendix S) and then entered into the Statistical Package for the Social Sciences (SPSS) version 28 software for data analysis. The quantitative data was analyzed using descriptive statistics. Measures of central tendency, a type of descriptive statistics, helped provide an accurate description, including percentages, means, and medians of the data set. The ORIC tool statements for commitment (1, 3, 5, 7, 8, 10 and 12) and confidants (2, 4, 6, 9 and 11) were grouped on 2 different spread sheets and analyzed per group. The 5As utilization questionnaire and ORIC tool was analyzed using Pearson's correlation coefficient and t-test to

Results

Collection of all data extended over 12 weeks. Thirty random charts were reviewed at baseline, 6 weeks and at 12 weeks. Patient data was extracted directly from the EHR and complied. No personal identifiers were recorded into the data file for patients and or staff. Staff data for confident, commitment, and demographics were entered into a Microsoft file using manual entry of questionnaire data. After data entry was complete, data was exported to IBM SPSS version 28 for analysis.

Staff Demographics

Demographics for staff are presented in Table 1 below. Descriptive statistics were computed for staff demographic variables of age, highest level of education achieved, staff role, length of service in a primary setting, length of service within the organization, and work status. A total of 24 staff agreed to participate. The most common age range was 46 to 55 years old (n = 8, 33.3%). The most common level of education was master's degree (n = 6, 25%) and associate degree (n = 6, 25%) and the least common is bachelor's degree (n = 2, 8.3%). Nurse Practitioners were the majority of staff roles (n = 5, 20.8%). Eight (33.3%) had more than 10 years of service in primary care but only two (8.3%) had more than 10 years at the organization. Most participants were full time (n = 17, 70.8%).

Table 1

Demographics for Staff Participants

Variable	n	%
Age		
18-25	1	4.2
26-35	4	16.7
36-45	5	20.8
46-55	8	33.3
56-65	5	20.8
Over 65	1	4.2

Highest Level of Education		
High School	5	20.0
Associate Degree	6	25.0
Bachelor's Degree	2	8.3
Master's Degree	6	25.0
Doctorate Degree	5	20.8
Staff Role		
Receptionist	4	16.7
Medical Assistant	2	8.3
License Practical Nurse	2	8.3
Registered Nurse	1	4.2
Radiology Technician	2	8.3
Billing and coding	1	4.2
Nurse Practitioner	5	20.8
Physician Assistant	3	12.5
Medical Doctor	3	12.5
Supervisor	1	4.2
Length of Service- Primary Setting (years)		
0-1	2	8.3
1-5	7	29.2
5-10	7	29.2
More than 10	8	33.3

0-1	6	25.0
1-5	8	33.3
5-10	8	33.3
More than 10	2	8.3
Work Status		
Full Time	17	70.8
Part Time	5	20.8
As Needed	2	8.3

Objective One

To examine objective one (Seventy percent of staff will feel committed and confident by indicating “somewhat agree” or “agree” and commit to the implementation of the tobacco cessation program within the clinic to improve patient care), descriptive statistics (*n*, %, *Mean*, *Median*) were computed on each item for the Commitment and Confident Survey. There were 23 staff that completed the commitment survey and 24 staff that completed the confident survey.

Table 2 represents proof goal of 70% was met with overall percentage of responses reporting commitment 82.6% (95 out of 115).

Table 2

Commitment Survey Results (N = 23)

Commitment Item	<i>n</i>	% reporting Somewhat Agree or Agree	<i>M</i>	Median
Committed to implementing this change.	23	100%	4.52	5
Will do whatever it takes to implement this change.	5	21.7%	2.74	3
Want to implement this change	22	95.7%	4.65	5
Are determined to implement this change.	23	100%	4.96	5
Are motivated to implement this change.	22	95.7%	4.52	5

Note. *M* = mean

Table 3 presents the overall percentage of responses reporting confident and the mean and median for each item. The overall percentage of responses reporting confident was 90% (158 out of 168), also supporting the goal rate of 75% confidence.

Table 3

Confident Survey Results (N = 24)

Confidence Item	<i>n</i>	% Reporting Somewhat Agree or Agree	<i>M</i>	Median
Feel confident that the organization can get people invested in implementing this change.	22	91.5%	4.7	5
Feel confident that they can keep track of progress in implementing this change.	23	95.8%	4.2	4

Feel confident that the organization can support people as they adjust to this change.	21	87.5%	4.2	4
Feel confident that they can keep the momentum going in implementing this change.	23	95.8%	4.4	4
Feel confident that they can handle the challenges that might arise in implementing this change.	24	100.0%	4.8	5
Feel confident that they can coordinate tasks so that implementation goes smoothly.	22	91.7%	4.3	4
Feel confident that they can manage the politics of implementing this change.	23	95.8%	4.6	5

Note. M = Mean

Pearson correlations were conducted to measure the strength of the linear relationship between the staff's commitment and confident scores. A scatter plot of the mean scores is displayed in Figure 2. The correlation coefficient was statistically significant, $r(21) = .663, p < .001$.

Figure 2

Confident and Commitment Scatterplot

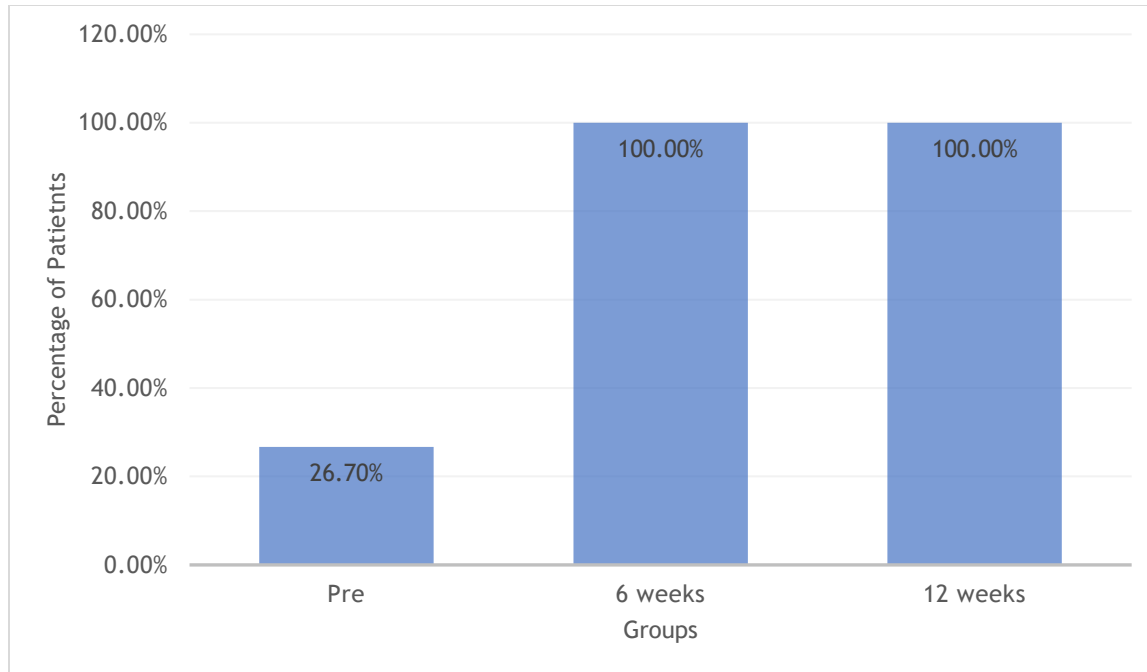

Objective Two

To examine objective 2a (Triage nurses will **Ask** all adults about tobacco use status 75% of the time and document patient response), descriptive statistics were conducted. Each item group had $n = 30$ charts were reviewed at baseline, week 6 and week 12. The findings show Ask was conducted for 8 (26.7%) at baseline. At 6 weeks and 12 weeks, the Ask was conducted for all 30 (100%) of patients. The objective was met for the week 6 and week 12, with more than 75% of adult tobacco users asked by the triage nurse about tobacco status, as seen in Figure 3.

Figure 3

Results for Ask Component of the 5As Model

To examine objective 2b (Triage nurses will **Advise** and **Assess** for willingness to quit for all active adult tobacco user patients 75% of the time and document the patient response), Descriptive statistics were conducted. The sample size for tobacco users was $n = 13$ for baseline, $n = 10$ at week 6, and $n = 10$ at week 12. Of the 13 patients in baseline, 2 (15.4%) were Advised and 4 (30.8%) were Assessed for readiness to quit tobacco use. For the week 6, all 10 (100%) were advised and assessed. Similarly, the week 12 group had a 100% rate ($n = 10$) for Advise and Assess. The objective was met for the week 6 and week 12, with more than 75% of adult tobacco users getting advised and assessed by the triage nurse, as seen in Figure 4.

Figure 4

Results for Advise and Assess Component of the 5As Model

Objective 2c (Health care providers will **Assist** all active tobacco users who express willingness to quit with counseling and or prescribing the FDA approved medication treatment 75% of the time and document their treatment plan) was examined using descriptive statistics. The baseline group had four patients that were assisted (13.3%). The week 6 and week 12 group, each had nine out of 10 patients (90.0%) that were assisted. The objective was met, as indicated by over 75% of week 6 and week 12 patients being assisted by the providers, as seen in Figure 5.

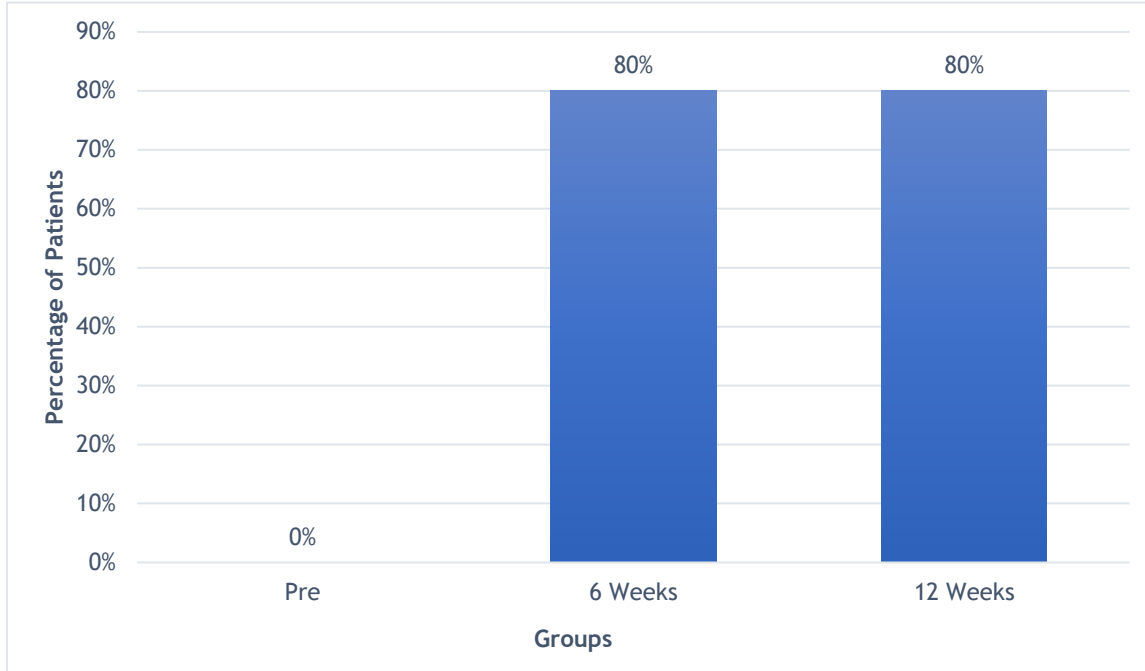

Figure 5

Results for Assist Component of the 5As Model

Objective 2d (Health care providers will **Arrange** at least one follow-up for those patients who express willingness to quit 75% of the time and document their treatment plan) was examined using descriptive statistics. Follow-up was not arranged for any baseline patients ($n = 0, 0.0\%$). The week 6 and week 12 intervention groups each had eight (80.0%) participants that were arranged for a follow-up. The objective was met, as indicated by a rate of 80% for the intervention patients, as seen in Figure 6.

Figure 6

Results for Arrange Component of the 5As Model

Objective 2e (Health care providers will select appropriate diagnostic, procedure, and billing codes based upon the documentation as related to findings and care provided 100% of the time) was examined using descriptive statistics. Diagnostic and procedure codes were documented for none of the baseline patients (0.0%), and eight of the patients at week 6 and week 12 intervention period (80.0%). Billing codes were documented for all patients in baseline ($n = 13$, 100%), and all patients at week and week 12 intervention group ($n = 10$, 100%). These findings (Figure 7) are evidence that objective 2e was partially met, as diagnostic and procedure codes did not meet the 100% goal, although the billing code documentation did meet the 100% goal.

Figure 7*Results for Documentation on Diagnosis and Procedures and Billing Codes*

Objective 2f (Data collected from the pre and post 5As utilization questionnaire) will increase by 50% over baseline. The baseline (pre) survey mean score was compared to the post survey mean scores and a % difference was computed. The mean score on a scale from 1 to 5 for the 5As utilization questionnaire at pre was 2.21 ($SD = .48$) and at post the mean was 4.12 ($SD = .29$). Higher scores are evidence of more utilization of the 5As. The increase from 2.21 to 4.12 is an 86.4% improvement, which achieves the objective of at least 50% improvement in the utilization scores (see Figure 8).

Figure 8

Results for 5As Utilization Questionnaire

An independent samples t-test was conducted and showed the mean score increase for the 5A utilization questionnaire was statistically significant from pre to post intervention (see Table 4).

The *p*-value was <.001.

Table 4

Variable	Pre			Post			t (36)	p
	M	SD	Median	M	SD	Median		
5As Utilization Questionnaire Score	2.21	0.48	2.22	4.12	0.29	4.00	-14.93	<.001

*5As Utilization Questionnaire Independent Samples t-test Results***Discussion**

Implementing this DNP project at a site that values quality improvement with committed and confident staff members, and a leadership team supportive of change facilitate project success. The findings revealed that implementing the Computer Facilitated 5As model increased asking, advising, assessing, assisting, and arranging for follow-up by clinicians to achieve tobacco cessation treatment. This is in line with past literature with comparable findings. For instance, Satterfield et al. (2018) found that computer-facilitated 5As increased primary care providers' screening and tobacco cessation treatment and adherence. Similarly, Moody-Thomas et al. (2015) demonstrated effective implementation of the 5As treatment model could improve tobacco abuse quit rate.

The findings can be explained by the fact that the intervention is practical considering tobacco cessation challenges. Also, a detailed education on utilization of the 5As framework was also delivered at individual staff convenience time and during their break period, increasing its adherence and efficacy. The practicability of the intervention is that patients who were active tobacco users were advised and assisted to quit with counselling and or medication. Even though complete abstinence was not evaluated and known in this project, those willing were counseled to quit, which could enable them to overcome challenges associated with quitting tobacco use.

Limitations

One of the limitations was a small sample size which affects the generalizability of the result. Also, the 5As Utilization Questionnaire data was self-reported hence may be biased. It is also possible that when people self-evaluate, they may be inclined to offer an outcome to show

that the process has been effective. Finally, the use of one facility may have increased homogeneity.

Implications

Practice

The Clinical Practice Guidelines for tobacco use disorder treatment offer numerous recommendations to health care providers and clinics on how to deliver evidence-based practice tobacco cessation treatments (Fiore et al., 2008). The guidelines also stressed the significance of all healthcare systems implementing approaches to help quickly identify, document, and treat every tobacco user at every encounter, especially primary care clinic visits. Recommendations from the Guidelines have increased tobacco cessation rates and abstinence (Park et al., 2015). Therefore, implementing a technology-enhanced system with an embedded 5As model is necessary to identify and treat all tobacco users.

Policy

Policy should explicitly outline the processes and expectations of each staff to identify challenging areas better and address them promptly. Unfortunately, most health care providers may not incorporate tobacco cessation interventions into their everyday practices leading to poor quality to care of tobacco users (Moody-Thomas et al., 2015; Satterfield et al., 2018). This clinic would need a tobacco cessation program policy to provide optimal tobacco use disorder treatment. In turn, the policy improves screening, compliance and revenue.

Safety and Quality

Chronic tobacco use is associated with morbidity and mortality (WHO, 2020). Assisting patients to full tobacco use abstinence improves the quality of life and health outcomes. Clinicians, particularly those in the primary care settings centers, plays a significant role in

assisting tobacco users in quitting (Satterfield et al., 2018). Therefore, it is imperative to provide an efficient and effective tobacco cessation program to properly treat tobacco use disorder like any other medical or mental health disorder.

Education

Tobacco use disorder treatment should include counseling and medication treatment as recommended by the guidelines (Fiore et al., 2008). The result of this DNP project has shown a 50% increase in staff's knowledge about tobacco use disorder after thorough education was provided. Clinicians must be trained and utilize both treatment approaches to help patients reach complete abstinence, improving quality of life and health outcomes. Incorporating yearly mandatory education about tobacco addiction screening and treatment would help enhance staff's knowledge and update any evidence-based changes.

Sustainability

The Computer Facilitated 5As model should be implemented by all healthcare facilities that seek to achieve tobacco cessation treatment. Also, health care managers should provide the required resources to support the implementation of the Computer Facilitated 5As model. In particular, there should be necessary technology and staff trained on implementing the model. Furthermore, there should be an evaluation of factors supporting or hindering the implementation of the Computer Facilitated 5As model. Implementers should ensure supporting factors are in place and solutions to address the hindering factors. In addition, a policy would be instrumental in promoting compliance with the 5As framework within the clinic. Lastly, for sustainability of success, it will be necessary to continue encouraging the change, track metric data to evaluate for compliance, and address limitations discovered in the implementation of the project.

Future Scholarship

Implementing an evidence-based practice tobacco cessation program would increase the assessment and treatment of tobacco use disorder. Also, it will improve quality of life and negative health consequences associated with tobacco use disorder. This DNP project indicates a continuation of the project interventions to correctly identify and treat active tobacco users to improve clinician engagement and health outcomes. Funding and future research are needed to replicate this quality improvement project in larger populations. This project did not evaluate the quit rate associated with the utilization of the 5As model. Further research is needed to evaluate the effect of 5As on quit rate and overall long-term tobacco cessation effect. The result of this project will be presented to the organization's leadership to persuade for the continuation of the practice. Current employer has 10 community health clinics. Collaboration with the leadership is planned to expand the project to larger community health clinics. Poster presentations at each clinic site is planned to engage larger staff.

Conclusion

The objective of this project was to develop and implement a tobacco cessation program protocol using the Computer Facilitated 5As (CF5As) model in the clinic within 12 weeks. The findings showed that staff were confident and committed to implementing the tobacco cessation program within the clinic to improve patient care. Further, the benchmarks for asking, advising, assessing, assisting, and arranging for follow-up by clinicians were all met. This showed that implementation of the Computer Facilitated 5As model increases asking, advising, assessing, assisting, and arranging for follow-up by clinicians to seek to achieve tobacco cessation care. In this regard, healthcare stakeholders, organizations, and practitioners should implement the Computer Facilitated 5As model within their facilities to increase screening and tobacco cessation.

Quality Improvement Project

Improving Utilization of the 5As in a Primary Care Clinic: Tobacco Cessation Treatment

Purpose

This project is a quality improvement project that intent to improve the treatment of tobacco use disorder among adults in a primary care clinic. The objective is to develop and implement a tobacco cessation program protocol using the Computer Facilitated 5As model in a primary care clinic within 12 weeks.

Inclusive Criteria

- Medical doctors, nurse practitioners, physician assistants, nurses, medical assistant, receptionist, radiology technicians, manager, billing staff and IT representation
- Patients 18 years and older
- Patients seen within the project 12 weeks implementation face

Participants will be ask to document the 5As in every patient encounter

- **Ask** - Identify and document tobacco use status for every patient at every visit .
- **Advise** - Urge every tobacco user to quit.
- **Assess** - Assess willing to make a quit attempt at this time?
- **Assist** - Use counseling and pharmacotherapy to help him or her quit.
- **Arrange** - Schedule follow-up to support recovery

Appendix K

Recruitment Script

Dear Participant,

My name is Binta Bojang. I am a Doctor of Nursing Practice student at Eastern Kentucky University. I am implementing a quality improvement project on tobacco screening and treatment.

This quality improvement project aims to increase the utilization of 5As five-step tobacco cessation screening and treatment among all the clinicians in the primary care clinic. The objective is to develop and implement a tobacco cessation program protocol using the Computer Facilitated 5As model in a primary care clinic within 12 weeks.

During this project, a new assessment will be added to the daily workflow within the current Electronic Medical Record (EMR) for each patient encounter. This assessment is called the 5As framework. The 5As framework consists of *Ask, Advise, Assess, Assist and Arrange*. During every patient encounter, the staff member triaging the patient will ask the patient about tobacco use, advise the patient on the benefits of quitting, and assess for patient's readiness to quit. The provider seeing the patient will assist the patients by providing counselling, resources and or recommending nicotine replacement medication. Provider will also recommend and arrange for follow ups if indicated. Additionally, the provider is expected to document the appropriate diagnosis code and the CPT code for each encounter.

Before you decide whether to accept this invitation to take part in the project, please ask any questions that come to mind now. Later, if you have questions about the project, you can contact the investigator, Binta Bojang at 301-379-8180 or binta_bojang@mymail.eku.edu. If you have any questions about your rights as a project volunteer, you can contact the staff in the Division of Sponsored Programs at Eastern Kentucky University at 859-622-3636.

Sincerely,
Binta Bojang
RN, CRNP, DNP Student
Principal Investigator

Appendix L

Request for Waiver

Eastern Kentucky University Institutional Review Board

Request for Waiver of Informed Consent Documentation

Informed consent is a foundational component of protecting human research subjects and is at the core of the IRB's ethical values. In general, all studies involving human subjects must include a formal informed consent process that is documented with signatures from participants. In a limited number of situations, however, Federal regulations permit an IRB to authorize a waiver of informed consent documentation. When a study is approved with a waiver of informed consent documentation, this means that signatures from subjects are not required on consent forms. However, such a waiver does not eliminate the ethical requirement to provide information to potential subjects and allow them to make an informed decision about voluntarily participating. Investigators are still required to follow a process of obtaining consent and to outline this process in the application for IRB review.

In unique situations where a study cannot be practicably carried out with informed consent documentation, this form may be used to request a waiver of the informed consent documentation requirements. If approved, the waiver will be specifically outlined in the approval notification.

1. Title of Study:

Addressing Tobacco Use with Improved Utilization of 5As Framework in Primary Care

2. Principal Investigator and Faculty Advisor:

Principal Investigator Name: Binta Bojang

Primary Faculty Advisor (required only if principal investigator is a student): Dr. Angela Wood

3. Category of Waiver Request:

Please indicate which of the following situations apply and respond to the items that follow each category.

- A.** The only record linking the subject and the research would be the informed consent form and the principal risk would be potential harm resulting from a breach of confidentiality. In this case, each subject (or legally authorized representative) must be asked whether the subject wants documentation linking the subject with the research, and the subject's wishes will govern.
- Describe the procedures to be followed for offering this choice to each subject.
Click to enter text.

- B.** The research presents no more than minimal risk of harm to subjects and involves no procedures for which written consent is normally required outside of the research context.
- Provide a justification describing how the proposed study meets this criteria.
The implementation of the project involves practices that are already in place and do not include experimental intervention. Therefore, there is minimal risk and very minimal ethical issues. No personal protected information of staff and or patients will be collected during the entire pre- and post-intervention data.
- C.** The subjects or legally authorized representatives are members of a distinct cultural group or community in which signing forms is not the norm, the research presents no more than minimal risk of harm to subjects, and an alternative mechanism will be used for documenting that informed consent was obtained
- Identify and provide background on the cultural group and cite references for views on signing forms.
 - Describe the alternative mechanism to be used for the documentation of informed consent.

4. Explain how the waiver will not adversely affect the rights and welfare of the subjects.

Tobacco use assessment and treatment is recommended for every patient encounter and will be done regardless of this project. No project results would affect clinical decisions about the individual's care.

5. Explain why the research could not practicably be carried out without the waiver.

The DNP project could not practicably be carried out without the waiver or alteration. For example, to answer the research question and background survey, the PI must view multiple medical records for retrospective data collection. The waiver is needed because no personal protective information will be collected and or stored.

Appendix M
Staff Education

Tobacco Cessation Program: Staff Education

Primary Investigator: Binta Bojang, CRNP-BC, DNP student
Eastern Kentucky University School of Nursing

Lesson Objective

- Enhancing the proficiency of the clinic staff in assessing and treating tobacco use disorder.
- Improve knowledge about the elements of 5 As.
- Enhance knowledge, awareness and engagement among all the clinical staff on the significance of effectively treating tobacco disorder.

Background

Tobacco use related diseases are one of the leading preventable causes of chronic diseases in the United States. In 2018, approximately 14% of U.S. adults currently used tobacco product.

- Tobacco related illness in the United States costs more than \$300 billion a year.
- Tobacco cessation reduces the risk for many adverse health effects.
- Interesting, over 50% of tobacco users try to quit each year but fail.
- Clinical guideline highly recommends the use of 5 As in treating tobacco use disorder among all adult patients

Reasons To Offer Tobacco Cessation

Patients who participate in tobacco cessation programs can:

- Save thousands of dollars each year by quitting smoking.
- Experience physical health benefits almost immediately upon quitting.
- Expect improvement in mood and anxiety levels after initial withdrawal symptoms are addressed.
- Increase their chance of quitting if they are also on nicotine replacement therapy or other cessation medication.

The 5 A's

Begin a quit-smoking intervention with a client in five easy steps.

- **ASK** – Document each client's tobacco use status at every visit.
- **ADVISE** – Urge every tobacco user to quit.
- **ASSESS** – Determine whether the tobacco user is willing to try quitting.
- **ASSIST** – Use counseling and pharmacotherapy to help willing clients quit.
- **ARRANGE** – Schedule follow-up phone calls or meetings, preferably the first week after the quit date

Medications Improve Quit Rates

- Nicotine patch, gum, or lozenge
- Nicotine nasal spray or inhaler
- Bupropion (Zyban)
- Varenicline (Chantix)

Diagnostic Coding for Tobacco Use Disorder

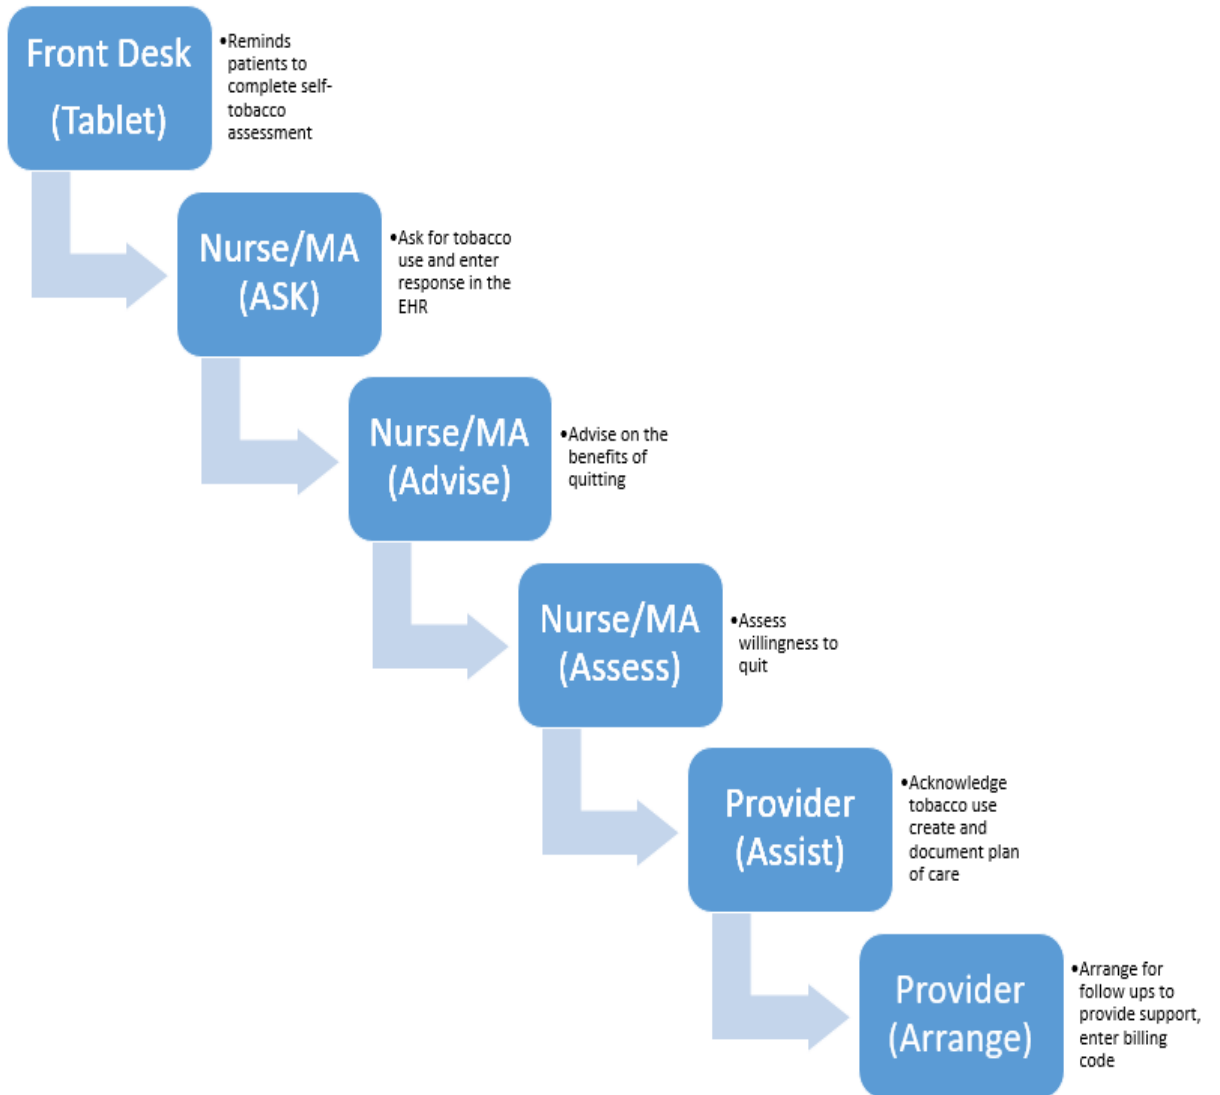

- Cigarettes •F17.21
- Chewing Tobacco •F17.22
- Other e-cigarettes •F17.29

Tobacco use Evaluation and Management Codes

- 99406 { Preventive medicine, smoking/tobacco use cessation counseling, greater than three minutes and up to ten minutes
- 99407 { Preventive medicine, smoking/tobacco use cessation counseling, intensive greater than ten minutes

TIPS FROM FORMER SMOKERS
CDC'S TIPS FROM FORMER SMOKERS® CAMPAIGN

Reasons to Quit Smoking

Everyone has their own reasons for quitting smoking. Maybe they want to be healthier, save some money, or keep their family safe from secondhand smoke. As you prepare to quit, think about your own reasons for quitting. Remind yourself of those reasons every day. They can inspire you to stop smoking for good. Whatever your reasons, you will be amazed at all the ways your life will improve when you become smokefree.

It's best to quit as soon as possible. This allows your body a chance to heal and reduces your risk for serious health problems, like heart attacks.

Here are a few reasons to quit you may want to consider:

Your Health and Appearance

- Your chances of having cancer, heart attacks, heart disease, stroke, and other diseases will go down.
- You will be less likely to get sick.
- You will breathe easier and cough less.
- Your skin will look healthier, and you will look more youthful.
- Your teeth and fingernails will not be stained.

Quitting will make you feel better and improve your health. But there are other reasons to quit that you may not have considered:

Your Lifestyle:

- You will have more money to spend.
- You can spend more time with family, catch up on work, or dive into your favorite hobby.
- You won't have to worry about when you can smoke next or where you can or can't smoke.
- Your food will taste better.
- Your clothes will smell better.
- Your car and home won't smell like smoke.
- You will be able to smell food, flowers, and other things better.

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention
CDC.gov/tips

August 2019

2019 Reasons to Quit Smoking

TIPS FROM FORMER SMOKERS CDC'S TIPS FROM FORMER SMOKERS® CAMPAIGN
Reasons to Quit Smoking

More reasons to quit that you may not have considered:

Your Loved Ones:

- You will set a great example for your kids; it takes a lot of strength to quit.
- Your friends, family, co-workers, and other loved ones will be proud of you.
- You will protect your friends and family from the dangers of secondhand smoke.
- Your children will be healthier.
- You will have more energy to do the things you love with friends and family.
- You will get healthy to make sure you are around to share in your family's special moments.

Make a list of all of the reasons you want to become smokefree. Keep the list in a place where you will see it often, like your car or where you used to keep your cigarettes. When you feel the urge to smoke, take a look at the list to remind yourself why you want to quit.

Background Survey

Directions: Please take a few minutes to answer the following questions by circling the answer the best describes you.

1. What is your age?
 - a. 18 - 25
 - b. 26 - 35
 - c. 36 - 45
 - d. 46 - 55
 - e. 56 - 65
 - f. 65+ years
2. What is your highest level of education achieved?
 - a. High school
 - b. Associate degree
 - c. Bachelor's Degree
 - d. Master's degree
 - e. Doctoral degree
3. What is your role?
 - a. Receptionist
 - b. Medical Assistant
 - c. License Practical Nurse
 - d. Registered Nurse
 - e. Radiology Technician
 - f. Billing and coding
 - g. Nurse Practitioner
 - h. Physician Assistant
 - i. Doctoral Degree
 - j. Supervisor
 - k. Other
4. How long have you been working in a primary setting?
 - a. 0 – 1 years
 - b. 1 – 5 years
 - c. 5 – 10 years
 - d. 10 + years
5. How long have been with the organization?
 - a. 0 – 1 years
 - b. 1 – 5 years
 - c. 5 – 10 years
 - d. 10 + years
6. What is your work status?
 - a. Full time
 - b. Part time
 - c. As needed
 - d. Contract
 - e. Volunteer

7. What is your biggest challenge to use the 5As?
